mail.google.com/mail/u/0/?tab=rm#starred/FMfcgzGmv8nVShdwKdjWSznFLcBvzp?projector=1&messagePartId=2e8feace_5ab49dd7_72079294_5...

Hello,

Please consider attached machine learning applications of

Please execute the attached Machine Learning application

To understand the above topics we prepare some informat

1. Marvellous Infosystems Machine Learning - Logis

2. Marvellous Infosystems Python - Supervised Mach

algorithm from sklearn.

Please download .csv file which is considered as a data set

Please execute and read each application that we ah

It is very important for a better understanding of Ma

Thanks & regards,

Piyush Manohar Khoslmur

Logistic Regression

Logistic regression predicts the probability of an outcome that can only have two values (i.e. a dichotomy). The prediction is based on the use of one or several predictors (numerical and categorical). A linear regression is not appropriate for predicting the value of a binary variable for two reasons:

- A linear regression will predict values outside the acceptable range (e.g. predicting probabilities outside the range 0 to 1)
- Since the dichotomous experiments can only have one of two possible values for each experiment, the residuals will not be normally distributed about the predicted line.

Linear Regression

Logistic Regression

On the other hand, a logistic regression produces a logistic curve, which is limited to values between 0 and 1.

Logistic regression is similar to a linear regression, but the curve is constructed using the natural logarithm of the "odds" of the target variable, rather than the probability. Moreover, the predictors do not have to be normally distributed or have equal variance in each group.

ing applications of "Logistic Regression with Titanic Dataset" that we discussed in the previous application and follow all steps of logistic regression.

are some informative documents.

Learning - Logistic Regression: It contains information about Logistic Regression.

Supervised Machine Learning using Logistic Regression Application 12: It contains information about the application of Logistic Regression. It is considered as a data set for the above application from <https://www.kaggle.com/uciemlsdata/titanic>.

ation that we already shared with you through some previous mails.

Understanding of Machine Learning.

In the logistic regression the constant (b_0) moves the curve left and right and the slope (b_1) defines the steepness of the curve. By simple transformation, the logistic regression equation can be written in terms of an odds ratio.

$$\frac{p}{1-p} = \exp(b_0 + b_1 x)$$

Finally, taking the natural log of both sides, we can write the equation in terms of log-odds (logit) which is a linear function of the predictors. The coefficient (b_1) is the amount the logit (log-odds) changes with a one unit change in x .

$$\ln\left(\frac{p}{1-p}\right) = b_0 + b_1 x$$

As mentioned before, logistic regression can handle any number of numerical and/or categorical variables.

$$p = \frac{1}{1 + e^{-(b_0 + b_1 x_1 + b_2 x_2 + \dots + b_p x_p)}}$$

There are several analogies between linear regression and logistic regression. Just as ordinary least square regression is the method used to estimate coefficients for the best fit line in linear regression, logistic regression uses maximum likelihood estimation (MLE).

to obtain the model coefficients that relate predictors to the target. After this initial function is estimated, the process is repeated until LL (Log Likelihood) does not change significantly.

$$\beta^1 = \beta^0 + [X^T W X]^{-1} \cdot X^T (y - \mu)$$

β is a vector of the logistic regression coefficients.

W is a square matrix of order N with elements $n_i \pi_i (1 - \pi_i)$ on the diagonal and zeros everywhere else.

μ is a vector of length N with elements $\mu_i = n_i \pi_i$.
